Auke Creek Weir 2004 Report

The Auke Lake system has endemic populations of pink, chum, sockeye and coho salmon, and supports populations of Dolly Varden char and cutthroat and steelhead trout. The National Marine Fisheries Service (NMFS), and its' predecessor agency, U.S. Bureau of Commercial Fisheries, began salmon research at Auke Creek, near Juneau, Alaska, in 1961. There are emigrant and immigrant counts of several species for the last four decades (Appendices 1 and 2). Pink salmon fry populations in Auke Creek were estimated annually, 1972-79, and counted at Auke Creek weir since 1980. Flyke nets were used to estimate sockeye salmon smolts leaving Auke Lake, and estimates are available for some years between 1961 and 1979. Total smolt counts are available since 1980. Chum salmon fry were counted annually since 1985. Coho salmon smolt estimates were made in 1976, 1977, and 1979, and the total coho smolt emigration was counted since 1980. Dolly Varden char and cutthroat trout were counted in 1970, and since 1980. Steelhead emigrants were counted since 1990. Weir counts of sockeye salmon adults at Auke Creek began in 1963; pink and chum salmon were counted 1967-68, and all salmon were counted since 1971. Chinook salmon returned to Auke Creek since 1987 as a result of releases of juveniles from other hatcheries. Immigrant Dolly Varden char and cutthroat and steelhead trout were counted since 1997.

Auke Creek has been the site of many research projects on wild and hatchery salmonids. The present weir at Auke Creek was constructed in 1980, and provided the capability to capture all emigrant and immigrant salmonids. Annual operation and maintenance costs associated with Auke Creek Research Station are provided by NMFS through the salmon research program of Auke Bay Laboratory. Projects at Auke Creek between 1971 and 1983 operated under several cooperative agreements. An interagency cooperative agreement relating to Auke Creek weir was established in 1983 between the NMFS, University of Alaska-Fairbanks (UAF), and Alaska Department of Fish and Game

(ADF&G). The agreement provides the authority to jointly fund a full-time person to assist with the operation of the fish counting weir at Auke Creek. The primary objective is to operate the weir on a daily basis and maintain the long-term data collections on migrant salmonids. The agreement was revised in December 2000, and is in effect through October 2005. Auke Creek weir usually operates from early March through late October. A report of fish counts from daily weir operation, and other information related to salmonid research involving the facilities at the weir is prepared each year. The annual fish count data are available in the Auke Creek data file at the NMFS Auke Bay Laboratory. Data collected on specific projects outside the scope of the cooperative agreement are usually not included in the annual report. Those data may be available from project investigators or their respective agencies. No fish were released from Auke Creek hatchery in 2004. All chinook and most chum salmon adults captured in 2004 were strays from other hatcheries. Nine pink/chum adult hybrids were captured at Auke Creek weir in 2004.

The emigration weir at Auke Creek was operated from March 2 through June 30 and captured pink, sockeye, chum, and coho salmon, Dolly Varden char, and cutthroat and steelhead trout leaving Auke Creek. All fish were counted and released. The first emigrants, pink and chum salmon fry, were captured March 3. Coho salmon smolts and cutthroat trout were marked and tagged during emigration.

The immigration weir was installed June 30 to capture salmonids entering Auke Creek. The weir was modified to capture small immigrants, specifically cutthroat and steelhead trout, Dolly Varden char, chinook salmon mini-jacks, and coho salmon juveniles. Before 1997, small fish passed through the adult weir panels and were not counted. Aluminum plates, 0.3 x 46 x 91 cm, with 1.3 x 10 cm horizontal slots were placed on the bottom half of the lowest weir panels to prevent passage of small fish. Small fish were captured in two trout traps attached to the upstream side of the weir. The

main weir and trout traps were lined with heavy plastic mesh, 6mm openings, to prevent passage of small fish. Salmon adults cannot enter the trout traps because of the small entrance openings. In accordance with the annual operation plan, various personnel assisted with the counting and processing of fish at the weir. Weir operations ended October 26, and the weir was removed from operation.

Water temperature in Auke Creek was measured daily at the weir site. Water temperatures were above average from early February through mid October, and near average for the rest of the year (Figure 1, Appendix 3). Overall, 2004 was the second warmest water-year on record for Auke Creek. Stream flows were low during March and April, and

decreased steadily throughout May and June. Flow from Auke Lake was extremely low in July and August, except from July 28-August 2, and after August 27. Stream flow in Auke Creek was measured in mid July at < 4 lpm. Surface temperatures of Auke Lake were >20°C for several weeks. Immigrations were delayed because of low stream flow and high water temperatures. There were no floods during the time the weir was operating this year.

Ice conditions on Auke Lake were within the range observed in other years. Auke Lake was ice free on April 5, 2004. The average ice free date for Auke Lake is April 18 (Figure 2, Appendix 4). Auke Lake was frozen over in late December 2003 and was about 95% frozen by December 27, 2004.

Figure 2. Dates of ice-out on Auke Lake, and trend line over all years.

Pink Salmon

Pink salmon spawn throughout the Auke Lake system mainly in Auke Creek and tributaries to Auke Lake and in the intertidal area downstream from the weir site. There are distinct runs of pink salmon in August and September, referred to as the early and late runs, in both the even and odd numbered years. Before 1963, Auke Creek upstream from the weir was mainly small rock and boulder substrate on bedrock, and there was probably limited area for spawning salmon. Spawning channels built in the upper reach of Auke Creek in 1963 provided about 1,000 m² of spawning area. The original streambed substrate was removed down to bedrock during channel construction. The channels were created by a series of 20x20cm timbers bolted together to form dams about 1 m high. The timbers were buttressed from the downstream side by concrete-filled sandbags. Each dam was filled with washed rock, mostly 5-10cm cobbles, purchased locally. Since 1963, floods washed large amounts of the cobbles out of the channels, and the streambed is reverting to bedrock and small boulder substrate. The streambed downstream from the weir is intertidal, and is mainly boulders, broken shale, and smaller gravel on bedrock. There are no complete counts of pink salmon at Auke Creek before the channels were built. Before the first return of hatchery pink salmon in 1973 the average adult run was about 2,600 fish.

Pink salmon fry populations were estimated in Auke Creek from 1972-80 by hydraulic censuses in the freshwater and intertidal areas. Weir counts of fry leaving the freshwater area began in 1980, and the hydraulic censuses stopped. The accuracy of hydraulic censuses of fry populations in Auke Creek is not known. The cobble and boulder substrate in Auke Creek makes it difficult to efficiently operate hydraulic sampling equipment, and the confidence intervals of fry estimates are large. The hydraulic censuses showed the average estimates and confidence intervals of freshwater and intertidal populations were $137,000 \pm 60,000$, and $63,000 \pm 29,000$.

In 2004, a total of 169,568 pink salmon fry were counted during the emigration from the freshwater area, about 50,000 more than the 1973-2003 average (Table 1). This was the second

highest number of odd-year brood fry, and only the hydraulic census estimate of the 1973 brood, the census was conducted in spring 1974, was higher. The average fry emigration for all years is 116,732 (Figure 3). The fry emigration was above average daily numbers through late April, after which the numbers decreased rapidly. A total of 22,950 fry emigrated in March, most fry emigrated in April, 146,337 fish, and 281 left in May (Figure 4, Appendix 5). No wild fry were marked or tagged in 2004. No hatchery fish were produced.

Figure 3. Number of wild pink salmon fry at Auke Creek.

Figure 4. The 2004 and 1973-2003 average emigration of pink salmon at Auke Creek.

There is a trend over the last three decades for Auke Creek pink salmon fry to emigrate earlier in the year, and the 2004 emigration followed that trend (Figure 5). The median date of the 2004 emigration was April 12. The average for all years is April 20; the earliest emigration was April 2, 1998 and the latest May 7, 1982.

Figure 5. Median emigration dates of pink salmon at Auke Creek, and the trend line over all years.

No hatchery fish were released from Auke Creek hatchery in 2004. Pink salmon were reared in many hatchery projects at Auke Creek, and fry were released annually from 1972-2000, except for 1994 and 1996. (Table 1). Enhancement experiments produced most of the pink salmon leaving Auke Creek during the first decade of hatchery experience, and returning hatchery fish were released to spawn in Auke Creek through 1984 and in 1996. Several genetic projects released small numbers of fry beginning in the mid-1980s, and all of these fry were to have been fin marked. Adults from genetic projects were not knowingly released in Auke Creek.

Pink salmon adults were counted at Auke Creek in 1967 and 1968, and annually since 1971. In 2004, 6,802 pink salmon adults were captured at Auke Creek weir (Table 1, Figure 6). The 2004 immigration was below average for Auke Creek wild fish, 7,528 adults, although it was 38% greater than the 2002 parent brood.

In 2004, 36 pink salmon adults were captured in late July, and most entered Auke Creek during the first week of September after being held out of the creek by an August drought that lasted until the 27th. The run was compressed in time this year, and nearly 90% of the pinks entered Auke Creek in the 12 days between August 27 and

September 7 (Appendix 6). Pre-spawning mortality in Auke Creek was high. Estimates from weir carcasses showed that approximately 50% of the females died before spawning. It was difficult to determine the timing of early and late spawners this year because of the overlap in run time caused by the drought. Based on sex ratio and slight decrease in daily counts, August 31 was considered the end of the early run, although there was not much certainty in that determination. The early run was 2,234 (1,092 males and 1,142 females) and the late run 4,568 (2,110 males and 2,450 females). The late September component of the run is almost gone. During the 1960's and 1970's it was not unusual to have hundreds of fish enter the creek daily through late September. Estimated return of pink salmon based on the fry counted at Auke Creek weir in 2003 is 7%.

Figure 6. Number of wild pink salmon adults at Auke Creek, 1967-68 and 1971-2004.

In 2004 the median date of pink salmon immigration was September 3, however the early and late median dates were less than a week apart. From 1967-1981 the average immigration was September 7, and since 1982 the average is August 27 (Figure 7).

Figure 7. Median immigration dates of pink salmon at Auke Creek. The lines are the averages of the periods.

Sockeye Salmon

Auke Lake sockeye salmon spawn in the larger tributaries and on submerged gravel beds in the lake. The production of sockeye smolts from Auke Lake was first estimated in 1961 at 90,816, the highest on record. From 1964 through 1979, wild smolt estimates ranged from 8,862 to 65,242. However, the pre-1980 smolt estimates lack continuity and some are known to be incomplete. Based on the pre-1980 adult counts, it is obvious there has been a significant decrease in the number of smolts since the 1960s and early 1970s. Since 1980, the entire smolt population was counted at Auke Creek weir, and the number of wild smolts ranged from 1,619 to 33,616. Hatchery-reared sockeye juveniles stocked in Auke Lake in 1974-1975 and 1987-1989 contributed to the smolt emigrations in 1975-77 and 1988-91. Sockeye enhancement from 1988-1992 included the release of age-zero (under-yearling) smolts reared in the hatchery at Auke Creek and net pens in Auke Bay.

In 2004, a total of 21,106 sockeye smolts emigrated from Auke Lake. The average number of wild smolts produced in Auke Lake, 1980-2004, is 17,264 (Figure 8, Table 2).

Figure 8. Number of sockeye salmon smolts leaving Auke Lake, 1980-2004.

Sockeye salmon emigration began in late April, 10 smolts, 20,989 emigrated in May, and 107 emigrated in June (Appendix 5). Emigration midpoint was May 15, 8 days earlier than average (Figure 9). Age-2 smolts migrated earlier than the age-1's, median dates May 14 and May 19 (Figure 10). All sockeye salmon smolts in 2004 were from natural spawning.

Figure 9. Median emigration dates of sockeye salmon smolts at Auke Lake. The line is the average.

Figure 10. Daily emigration of sockeye salmon at Auke Lake, 2004. Daily numbers are not stacked in figure.

Scale analysis revealed that 30% of the 2004 smolts, 6,292 fish, were age-1 (2002 brood), and 70%, 14,814 fish, age-2 (2001 brood). The 2001 brood has completed the freshwater phase of its' life history, and produced a total of 26,232 smolts, nearly 10,000 fish above the 24-year average of 17,639 (Figure 11). The 2002 brood has produced only age-1 smolts; the age-2 smolts will emigrate in 2005.

Figure 11. Number of age-1 and -2 sockeye smolts, by brood year, leaving Auke Lake.

Average size of age-1 and -2 sockeye salmon smolts from Auke Lake in 2004 were quite different from each other. Age-1 smolts averaged 81 mm and 4.5 gm, and age-2 smolts were 111 mm and 11.2 gm. The averages for age-1 and -2 sockeye smolts from Auke Lake are 76 mm and 3.7 gm and 106 mm and 11.5 gm.

Over the last 4 decades there was a trend of increasing size of sockeye smolts at Auke Lake (Figure 12). This trend is most noticeable in the average weights. For the periods 1961-1980, 1981-1990, and 1991-2004, age-1 smolts averaged 2.4, 4.3, and 4.3 gm, an 87% average gain between the first and second periods, and no change between second and third. The heaviest age-1 smolts, 6.8 gm, were in 1998. There were few age-2 smolts produced from 1961-1980, and the average was 4.5 gm. For the 1981-1990 and 1991-2004 periods, age-2 smolts averaged 9.5 and 16.8 gm. Average weight of age-2 smolts increased 111% between the 1961-1980 and 1981-1990 periods, and 77% between the 1981-1990 and 1991-2004 periods. From 1980 through 2004, the weight of age-1 and -2 sockeye smolts, estimated from linear regression lines of annual average weights, increased 0.8 and 3.7%/yr.

Figure 12. Average weight of age-1 and -2 sockeye salmon smolts leaving Auke Lake, by emigration year. The lines are linear trends for each age group.

There is a trend of increasing proportion of age-2 smolts produced from each brood year of Auke Lake sockeye salmon. Before 1980, age-2 smolts represented <5% of brood year production, and some broods produced no age-2 smolts. Since the 1980 brood year, the average proportion of age-2 smolts has reached 54% of the total brood year production (Figure 13).

Figure 13. Proportion of age-2 sockeye salmon smolts leaving Auke Lake, by brood year. The line represents the trend smoothed by local regression.

Total biomass-zooplankton models indicate Auke Lake has the capacity to produce about 350 kg of smolts annually. The total biomass of sockeye smolts (estimated total weight of all smolts in a migration year) from Auke Lake in 2004 was 194 kg. This was greater than the average of 149 kg for Auke Lake smolts for the years data are available (Figure 14). The 2004 smolt biomass was above average because of the increase in number of age-2 smolts.

Figure 14. Total annual biomass of sockeye salmon smolts leaving Auke Lake.

One measure of freshwater survival, the number of smolts produced per spawner, indicates that for Auke Lake sockeye, 1978-2001 brood years, only 7 broods produced 10 or more smolts per spawner, and the average over the last 24 broods is 8 smolts (Figure 15). The 2001 brood produced a total of 6.6 smolts per spawner. The 2002 brood produced 2.2 age-1 smolts per spawner; however, that production is expected to increase when the age-2 smolts emigrate in 2005.

Figure 15. Number of sockeye salmon smolts produced per brood year spawner at Auke Lake. The 2002 brood will produce age-2 smolts in 2005.

Sockeye salmon adults were counted annually at Auke Creek since 1963. From 1963 through 1981 sockeye escapements averaged about 7,000 adults, nearly 3 times greater than since 1982 (Figure 16). During the late 1970s the escapements declined, and, since 1982, the average return of wild fish was about 2,500. Sockeye enhancement research at Auke Creek hatchery, which used Auke Lake sockeye from the 1973-1974 and 1986-1991 broods, boosted subsequent escapements. Progeny from enhancement programs produced 4,600 and 18,000 adult sockeye to the Auke Creek escapements in 1977-1980 and 1990-1995, respectively. No hatchery sockeye have returned to Auke Creek since the enhancement program ended in 1995.

In 2004, 2,958 adult and 20 jack sockeye salmon returned to Auke Creek. The adult run was greater than the average wild run since 1982, but less than the historical average for all years, 4,567 adults. Most sockeye adults, 2,761 fish, migrated upstream in July (Appendix 6). Estimated survival, smolt to weir recovery of adults, for 2004 returns was 14%.

Chum Salmon

It is not known if chum salmon are native to Auke Creek or were originally strays from other local systems. Probably few chum salmon were ever produced in the Auke Lake system, although adults were observed in all spawning areas, including the intertidal. Chum salmon adults were counted at Auke Creek in 1967 and 1968, and since 1971. The average run to Auke Creek before NMFS enhancement experiments was 20 adults. Chum salmon fry were observed during the 1972-1976 emigrations, but were not counted. In 1976, NMFS started chum salmon enhancement projects, and examined the use of a small population for brood stock development, marine survival of juveniles, and age heritability. Hatchery chum salmon fry were released in 1977-1984, and 1986. All hatchery fry, except in 1984, were marked by ventral fin clip, or adipose fin clip and coded wire tag. No adults were released in Auke Creek from 1976-1983, and none spawned in the intertidal area. In those years all chum adults were captured and spawned for hatchery incubation, thus, no wild fry were captured at Auke Creek from 1977-1984. Since 1994, most or all chum salmon adults at Auke Creek were strays from releases of Macaulay hatchery juveniles at Amalga Harbor and other release sites.

In 2004, 1,425 chum salmon fry and 3,211 adults were counted and released at Auke Creek (Table 3). About 65% of the fry emigrated in March, about three weeks earlier than the pink salmon (Appendix 5). The midpoint of emigration was March 26. Based on run timing and number of chum salmon adults, it was suspected that most of the adults were strays from Macaulay hatchery releases. Before 1994, chum salmon in Auke Creek immigrated after mid August, usually during the last week of August and early September. In 2004, the 16 chum salmon that entered Auke Creek after the third week of August were counted as Auke Creek fish.

¹Estimated Macaulay hatchery-reared chums that strayed to Auke Creek.

Coho Salmon

Coho salmon spawn in the tributaries to Auke Lake and in the upper 100-m of Auke Creek. Juvenile rearing occurs in Auke Lake and probably most of the watershed, although the exact areas are not known. Total smolt numbers were estimated in 1976, 1977, and 1979, the first years when smolts were adipose fin clipped and tagged with coded wires (Table 4). Smolts were not counted or tagged in 1978. The total coho smolt emigration was counted since 1980. In 1976, 1977, and 1979 the total number of smolts was estimated from the return of jacks and adults from each smolt cohort. In the return years 1976-1980 there were marked and unmarked coho salmon from Auke Creek, and strays from enhancement projects in the Juneau area. The number of Auke Creek smolts was estimated after determining the number of marked and unmarked stray jacks and adults at the weir, and subtracting the latter two from the total immigration. The number of unmarked, Auke Creek smolts was estimated from the ratio of marked smolts and marked and unmarked jacks and adults of Auke Creek origin. Coho adults were counted in 1967, and since 1971. Before 1980, low-height weirs captured salmon adults at Auke Creek. Those weirs were often under water during floods, and some pre-1980 data may be incomplete. Coho salmon were spawned for hatchery incubation, 1978, 1980-1984, and 1996-1997, and all fish were tagged with coded wires and marked with an adipose and ventral fin clip to distinguish them from wild smolts. All hatchery coho jacks and adults with the double fin marks were killed when they returned to Auke Creek.

There is a trend of decreasing coho salmon smolt production at Auke Lake. A total of 4,581 coho salmon smolts left Auke Lake in 2004 (Figure 17). The highest total smolt count was 10,022 in 1980; the average total count is 6,117 (Table 4). In 2004, 4,572 smolts were tagged with coded wires and marked by adipose fin clip. Average sizes of age-1 and -2 smolts were 107 mm and 12 gm and 123 mm and 17 gm. Samples collected throughout the run revealed that 1,856 smolts were age-1 (2002 brood) and 2,725 were age-2 (2001 brood). Total production of smolts from the 2001 brood was 4,764 fish, and the

average production of the 1978-2001 broods is 5,934 smolts.

Coho smolts began emigration during the first week of May, and the emigration midpoint was May 16. The average emigration midpoint of coho smolts at Auke Creek is May 20 (Figure 18). Emigration of age-1 smolts was later than age-2 smolts, and emigration midpoints of age-1 and -2 smolts were May 22 and May 14 (Figure 19).

Figure 17. Number of coho salmon smolts at Auke Creek, 1980-2004. The line is the trend smoothed by local regression.

Figure 18. Median emigration dates of coho salmon at Auke Creek, 1980-2004.

Figure 19. Daily emigration of coho salmon at Auke Creek, 2004. Numbers are not stacked in figure.

The 2004 immigration of coho salmon at Auke Creek included adipose marked and unmarked jacks and adults, and totaled 226 jacks and 416 adults. The jack run was about 60 fewer than average (Figure 20). The adult run was 300 fish fewer than average, and one of the lowest on record (Figure 21). A total of 210 jacks and 412 adults were adipose fin marked, both less than average (Table 4). Most jack and adult coho salmon entered Auke Creek before the end of September. Coded wire tags were collected from carcasses recovered at the weir. All tags were from the Auke Lake stock of coho salmon. The origin of the 4 unmarked jacks and 16 unmarked adults is not known. Immigration of the marked fish was earlier than the unmarked. Most marked fish entered Auke Creek before the last week of September, and the unmarked fish did so from late September through October.

Harvest of coho salmon from Auke Creek was determined from recovery of coded wire tags in commercial and sport fishery port sampling programs. In 2004, the harvest of Auke Creek coho salmon was estimated at 320 adults, a 43.7% harvest rate. Average harvest and harvest rate of Auke Creek coho salmon is 495 adults and 42%.

Total survival of the coho salmon smolts tagged at Auke Creek in 2003 was 26.9% (jacks returned in 2003 and adults in 2004). Survival was estimated from the number of smolts marked at Auke Creek, and the number of marked jacks and adults at the weir and adults in the fishery. Total survival was the combined return of jacks 6.2% (returned in 2003), adults at the weir 11.7%, and adults harvested 9.1% (Figure 22, Table 4). The survival to jacks was the second highest on record. Combined survival to adults, weir plus fishery (excluding jacks), was 20.7%, slightly above the 20% average for Auke Creek.

Some smolts return as jacks the same year they emigrate at Auke Creek. In 2004, the 210 marked jacks at Auke Creek represented a survival of 4.6%; slightly above average of 4.1% (Table 4).

In 2004, immigrant coho salmon juveniles were intentionally captured at Auke Creek weir. A total of 90 were caught and examined for missing adipose fin. One fish was fin clipped and had a coded wire tag. The fish was from Chilkat River, near Haines, from a group of 7,000 coho juveniles

tagged and released on or before May 29, 2004. The fish was 147 mm and 38.9 gm when captured at Auke Creek weir on September 10, 2004.

Figure 20. Coho salmon jacks at Auke Creek, 1971-2004.

Figure 21. Weir counts and fishery harvest of Auke Creek coho salmon adults.

Figure 22. Ocean survival of coho salmon smolts from Auke Creek. Survivals are for tagged fish by year of emigration. The lines are not stacked in the figure.

Table 4. Annual numbers of Auke Creek coho salmon smolts, jacks, and adults. Smolt data are total number and number released with coded wire tags. Weir recoveries are total number and number of tagged jacks and adults. Adults recovered in the fishery are tagged fish. Survival data are for tagged smolts by year of smolt migration, e.g., smolts tagged in 1976 returned as jacks in 1976 and as adults in 1977.

Dolly Varden Char

The Auke Lake system is important for spawning, rearing, and over-wintering Dolly Varden char in the Juneau area. Emigrants were counted in 1970 and since 1980, but spawner numbers and smolt production are not known. Emigrants were marked or tagged in 1970, 1980, 1983, and 1990, and marked fish were observed in subsequent years. Marked fish captured at Auke Creek, 1998-2000, were probably marked at Windfall Lake in 1997.

Auke Creek Dolly Varden char abundance is in a decreasing trend that began in 1996 (Figure 23). The 2004 emigration of 3,955 Dolly Varden at Auke Creek was the lowest since 1985, and less than the average of 6,214 (Table 5). Little emigration occurs in March, only 6 left Auke Lake during March 2004 (Figure 24). Daily counts never exceeded 50 fish until the last week of April, and 85% of the run occurred between April 27 and May 11 (Appendix 5). The midpoint of emigration was May 3, and the average midpoint for all years is May 8 (Figure 25). Dolly Varden were sampled daily throughout the emigration by measuring the length of every tenth fish. Larger fish emigrated earlier, and average length decreased weekly from 360 mm to 138 mm during the main part of the emigration (Figure 26). Overall, the average length of emigrants was 244 mm. All fish were checked for marks or tags, none were found.

Figure 23. Emigrant Dolly Varden char at Auke Creek. The curved line is the abundance trend smoothed by local regression.

Immigrant Dolly Varden were counted at Auke Creek since 1997. A total of 2,564 Dolly Varden were captured at the upstream weir in 2004. The average number of Dolly Varden immigrants at Auke Creek, 1997-2004 is 4,276

(Table 5). The immigration was slowed or stopped by high water temperatures and droughts in July and August (Appendix 6).

¹ Years Dolly Varden were marked and/or tagged at Auke Creek

² Marked Dolly Varden recovered but not marked at Auke Creek

Cutthroat and Steelhead Trout

Little was known of the life history of cutthroat trout in the Auke Lake system before the start of tagging programs in 1994 and lake population estimates in 1998. It is apparent that Auke Lake cutthroat trout have the most complex life history of any fish in the system. Recent studies at Auke Creek and Auke Lake have produced world class information on these fish. Anecdotal information suggests the pre-1960 population of cutthroat trout in Auke Lake was larger than it is now. Emigrant cutthroat trout were counted in 1970 and since 1980. Immigrants were counted since 1997. Mature emigrants were spawned in 1981, 1982, 1985, 1986, 1991, and 1993 for hatchery incubation. The resulting progeny were fin marked and released in Auke Lake, and hatchery fish were seen in subsequent years (Table 6).

Auke Creek cutthroat trout emigrants are in a decreasing trend that began in 1996 (Figure 27). A total of 136 emigrant cutthroat trout were counted in 2004, less than the average 250. In 2004, most cutthroat emigrated in May (Figure 28, Appendix 5), and midpoint of emigration was May 10. The average emigration date is May 16. All cutthroat were examined for a missing adipose fin and dye marks on the ventral, pectoral or anal fins. Fish missing the adipose fin were electronically checked for a passive integrated transponder (PIT) tag. A total of 37 cutthroat trout were missing their adipose fin when they left Auke Lake this year: 24 were recaptures from previous emigrations (1 tagged in 2001, 5 in 2002, and 18 in 2003), and 13 were recaptures from tagging in Auke Lake (6 tagged in 2002, and 7 in 2003). The 99 unmarked fish were

Figure 27. Number of emigrant cutthroat at Auke Creek. The line is the abundance smoothed by local regression.

marked by excision of the adipose fin, and tagged with a numbered PIT tag, then released. All cutthroat trout emigrants were measured for fork length. The larger fish emigrated earlier than smaller ones. The average weekly size during the main part of the emigration decreased from about 285 mm to about 245 mm (Figure 29). Average length of emigrant cutthroat trout in 2004 was 261 mm.

Figure 28. Average and 2004 daily emigrations of cutthroat trout at Auke Creek.

Figure 29. Median emigration dates of cutthroat trout at Auke Creek. The line is the average date: May 16.

Figure 30. Fork lengths of cutthroat trout emigrants at Auke Creek, 2004. The line is the trend line across all points.

In 2004 there were 91 immigrant cutthroat trout at Auke Creek, about 40% of average. No cutthroat immigrated in July or August, 75 did so in September, and 16 in October (Appendix 6). All were examined for adipose fin marks and PIT tags before release. A total of 25 immigrants were missing the adipose fin and had a PIT tag, and 66 were unmarked. Estimates of marine residence, seasonal growth, and growth rate were made from individual PIT tagged immigrants captured in 2004. Seasonal growth and growth rate were estimated for the period between emigration and

immigration. The average marine residence of tagged cutthroat trout in 2004 was 132 days, range 114-152 days. Average growth was 65 mm, range 39-101 mm, and average growth rate was 0.44 mm/day, range 0.31-0.73 mm/day.

Steelhead trout juveniles were captured at Auke Creek in 2004. Four emigrants were captured during the middle two weeks of May, and their fork lengths ranged from 195-232 mm. Two steelhead trout immigrants were captured in Auke Creek in 2004. None of the steelhead were marked or tagged.

Chinook Salmon

Chinook salmon are not native to the Auke Lake system. Chinook captured at Auke Creek are hatchery fish from releases of juveniles in the Juneau area, including Auke Bay near the mouth of Auke Creek. These releases began as a 3-year cooperative study in 1986 to examine survival and homing and straying of hatchery chinook. The original study plan and fish transport permit required that all chinook be killed when they entered Auke Creek. This was to prevent the possible chinook-sockeye disease interactions, particularly infectious hematopoietic necrosis virus. The project continues under an arrangement between Sport Fish Division, ADF&G, and Douglas Island Pink and Chum Incorporated. Juveniles were released near Auke Creek in 2004.

At Auke Creek, chinook are captured at the weir, and classified as mini-jacks or adults based on size. All mini-jacks are males, ≤ 250 mm fork length, that mature and return to fresh water the same year they were released as smolts. Adults are >250 mm and remain at large for one year or more. All chinook are killed at the weir. As agreed at the 2003 annual meeting, chinook were not examined for marks or tags in 2004.

In 2004, the immigration of chinook adults at Auke Creek was restricted by the low stream flow and high temperatures during July and August. A total of 46 chinook salmon adults and 232 mini-jacks were captured at the weir (Table 7). The number of chinook adults was the second lowest at Auke Creek (Figure 28). Most chinook adults were captured between August 28 and September 6 (Appendix 6). All chinook were killed and offered to local charities.

Figure 31. Number of chinook salmon at Auke Creek.

Table 7. Number of chinook salmon at Auke Creek, 1987-2004. Mini jacks returned the same year of smolt release, and adults are 1-ocean or older. Fish were not sampled for fin marks after 2002.
